

Intermediate Code Generation

4 Source languages
3 Target machines

4 front ends +
4x3 optimizers +
4x3 code generators

4 Source languages
3 Target machines

4 front ends +
1 optimizer +
3 code generators

Why Intermediate Code?

Without intermediate code generator -

-For **m** languages and **n** target machines, we need to write **m** front-ends, **m \times n** optimizers, and **m \times n** code generators.

-Reuse is not possible.

With intermediate code generator -

-A machine independent code optimizer can be written

-**m** front ends, **n** code generators and 1 optimizer

Without Intermediate Code Optimizer

Three Address Code

- Simple instructions
- LHS is the target and RHS has at most **two operands and one operator**
- RHS operands can be either variables or constants

Example:

$a + b * c - d / (b * c)$

3-address code

1	$t1 = b * c$
2	$t2 = a + t1$
3	$t3 = b * c$
4	$t4 = d / t3$
5	$t5 = t2 - t4$

Quadruples

op	arg ₁	arg ₂	result
*	b	c	t1
+	a	t1	t2
*	b	c	t3
/	d	t3	t4
-	t2	t4	t5

Triples

	op	arg ₁	arg ₂
0	*	b	c
1	+	a	(0)
2	*	b	c
3	/	d	(2)
4	-	(1)	(3)

Syntax tree

DAG

Three Address Code

- Assignment instructions:

a = b biop c

a = uop b

- biop is any binary arithmetic, logical, or relational operator
- uop is any unary arithmetic (-, shift, conversion) or logical operator (~)

- Copy instruction:

a = b

- Jump instructions:

goto L

if t goto L

- L is the label of the next three-address instruction to be executed, t is a boolean variable, a and b are either variables or constants

Three Address Code

- Functions:

func begin <name>	//beginning of the function
func end	//end of a function
param p	//place a value parameter p on stack
refparam p	//place a reference parameter p on stack
call f, n	//call a function f with n parameters
return	//return from a function
return a	//return from a function with a value a

Three Address Code

- Indexed copy instructions:

$a = b[i]$ $//a$ is set to $\text{contents}(\text{contents}(b) + \text{contents}(i))$

$a[i] = b$ $//i$ th location of array a is set to b

- Pointer assignments:

$a = \&b$ $//a$ is set to the address of b , i.e., a points to b

$*a = b$ $//\text{contents}(\text{contents}(a))$ is set to $\text{contents}(b)$

$a = *b$ $//a$ is set to $\text{contents}(\text{contents}(b))$

Three Address Code

- C-Program

```
int a[10], b[10], dot_prod, i;  
dot_prod = 0;  
for (i=0; i<10; i++) dot_prod +=  
a[i]*b[i];
```

dot_prod = 0;	T7 = addr(b)
i = 0;	T8 = i*4
L1: T1 = i>10	T9 = T7[T8]
T2 = i==10	T10 = T6*T9
T3 = T1 && T2	T11 = dot_prod+T10
if T3 goto L2	dot_prod = T11
T4 = addr(a)	T12 = i+1
T5 = i*4	i = T12
T6 = T4[T5]	goto L1
	L2:

Single-Static-Assignment (SSA)

- Another intermediate representation
- Facilitates certain code optimizations
- All assignments are to variables with distinct names

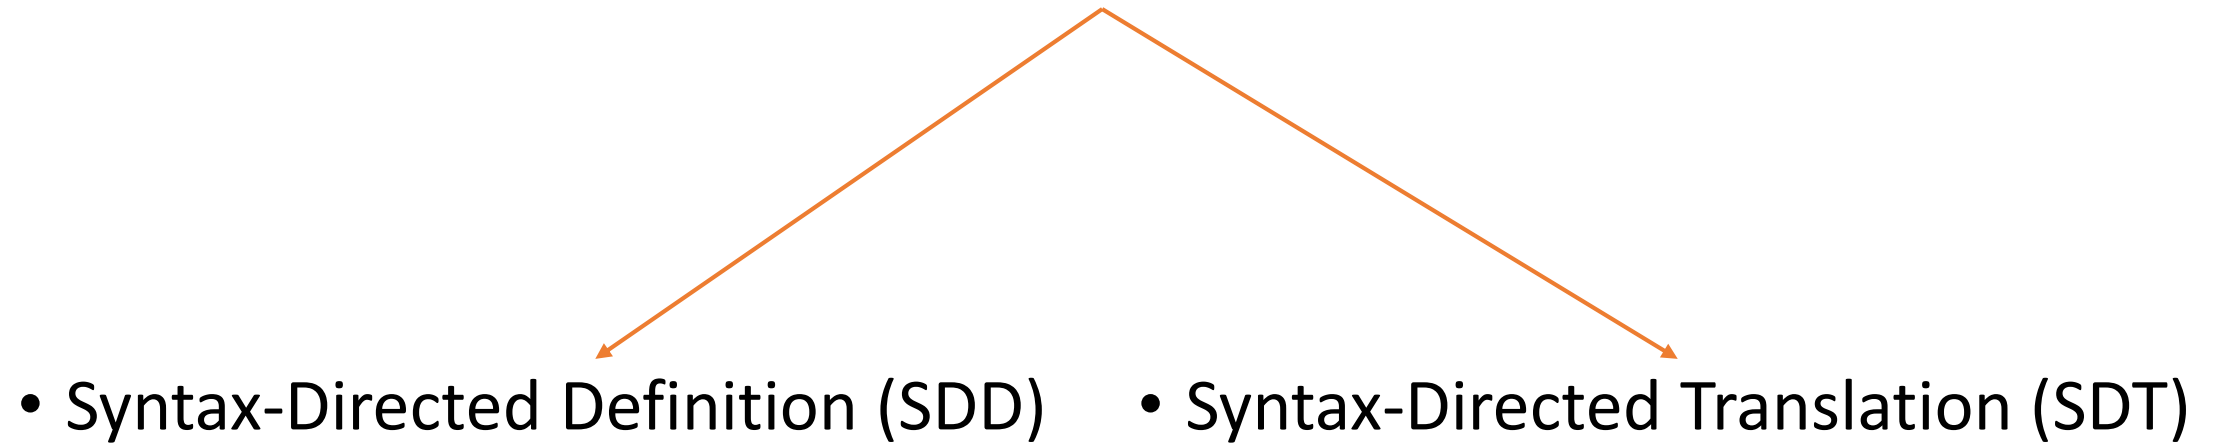

```
p = a + b
q = p - c
p = q * d
p = e - p
q = p + q
```

(a) Three-address code.

```
p1 = a + b
q1 = p1 - c
p2 = q1 * d
p3 = e - p2
q2 = p3 + q1
```

(b) Static single-assignment form.

Translations of Statements and Expressions

Three Address Code for Expressions

PRODUCTION	SEMANTIC RULES
$S \rightarrow \text{id} = E ;$	$S.code = E.code \parallel$ $gen(top.get(\text{id.lexeme}) \neq E.addr)$
$E \rightarrow E_1 + E_2$	$E.addr = \text{new Temp}()$ $E.code = E_1.code \parallel E_2.code \parallel$ $gen(E.addr \neq E_1.addr \neq E_2.addr)$
$ - E_1$	$E.addr = \text{new Temp}()$ $E.code = E_1.code \parallel$ $gen(E.addr \neq \text{'minus'} E_1.addr)$
$ (E_1)$	$E.addr = E_1.addr$ $E.code = E_1.code$
$ \text{id}$	$E.addr = top.get(\text{id.lexeme})$ $E.code = ''$

Stores address of E
(e.g. temp variable etc.)

Stores three-address code
For E

PRODUCTION	SEMANTIC RULES
$S \rightarrow \text{id} = E ;$	$S.\text{code} = E.\text{code} $ $\text{gen}(\text{top.get}(\text{id.lexeme}) \neq E.\text{addr})$
$E \rightarrow E_1 + E_2$	$E.\text{addr} = \text{new Temp}()$ $E.\text{code} = E_1.\text{code} E_2.\text{code} $ $\text{gen}(E.\text{addr} \neq E_1.\text{addr} + E_2.\text{addr})$
$ - E_1$	$E.\text{addr} = \text{new Temp}()$ $E.\text{code} = E_1.\text{code} $ $\text{gen}(E.\text{addr} \neq \text{'minus'} E_1.\text{addr})$
$ (E_1)$	$E.\text{addr} = E_1.\text{addr}$ $E.\text{code} = E_1.\text{code}$
$ \text{id}$	$E.\text{addr} = \text{top.get}(\text{id.lexeme})$ $E.\text{code} = ''$

Builds an instruction

Returns a temporary
variable

Current Symbol Table

An example: $a = b + c + (d)$

<u>Stack</u>	<u>Production Rule</u>	<u>Semantic Rules</u>	<u>Action</u>	<u>'gen' Output</u>
$id = id$	$E \rightarrow id$	$E.addr = top.get(id.lexeme)$ $E.code = ''$	$E.addr = b$	
$id = E_1 + id$	$E \rightarrow id$	$E.addr = top.get(id.lexeme)$ $E.code = ''$	$E.addr = c$	
$id = E_1 + E_2$	$E \rightarrow E_1 + E_2$	$E.addr = new Temp()$ $E.code = E_1.code E_2.code $ $gen(E.addr '=' E_1.addr '+' E_2.addr)$	$E.addr = t1$	$t1 = b + c$
$id = E + (id$	$E \rightarrow id$	$E.addr = top.get(id.lexeme)$ $E.code = ''$	$E.addr = d$	
$id = E + (E_1)$	$E \rightarrow (E_1)$	$E.addr = E_1.addr$ $E.code = E_1.code$	$E.addr = d$	$t1 = b + c$

An example: $a = b + c + (d)$

<u>Stack</u>	<u>Production Rule</u>	<u>Semantic Rules</u>	<u>Action</u>	<u>'gen' Output</u>
$id = id$	$E \rightarrow id$	$E.addr = top.get(id.lexeme)$ $E.code = ''$	$E.addr = b$	
$id = E_1 + id$	$E \rightarrow id$	$E.addr = top.get(id.lexeme)$ $E.code = ''$	$E.addr = c$	
$id = E_1 + E_2$	$E \rightarrow E_1 + E_2$	$E.addr = new Temp()$ $E.code = E_1.code E_2.code $ $gen(E.addr '=' E_1.addr '+' E_2.addr)$	$E.addr = t1$	$t1 = b + c$
$id = E + (id$	$E \rightarrow id$	$E.addr = top.get(id.lexeme)$ $E.code = ''$	$E.addr = d$	
$id = E + (E_1)$	$E \rightarrow (E_1)$	$E.addr = E_1.addr$ $E.code = E_1.code$	$E.addr = d$	$t1 = b + c$

An example: $a = b + c + (d)$

<div>Top of stack</div>				
<u>Stack</u>	<u>Production Rule</u>	<u>Semantic Rules</u>	<u>Action</u>	<u>'gen' Output</u>
$id = E_1 + E_2$	$E \rightarrow E_1 + E_2$	$E.addr = \text{new Temp}()$ $E.code = E_1.code \parallel E_2.code \parallel$ $\text{gen}(E.addr '=' E_1.addr '+' E_2.addr)$	$E.addr = t2$	$t2 = t1 + d$
$id = E$	$S \rightarrow id = E$	$S.code = E.code \parallel$ $\text{gen}(top.get(id.lexeme) '=' E.addr)$	$top.get$ returns a	$a = t2$

Final Code

```
t1 = b + c  
t2 = t1 + d  
a = t2
```

Incremental Translation

$S \rightarrow \mathbf{id} = E ; \quad \{ \text{gen}(\text{top.get}(\mathbf{id.lexeme}) \text{'=' } E.addr); \}$

$E \rightarrow E_1 + E_2 \quad \{ E.addr = \mathbf{new Temp}();$
 $\quad \text{gen}(E.addr \text{'=' } E_1.addr \text{'+' } E_2.addr); \}$

$\mid - E_1 \quad \{ E.addr = \mathbf{new Temp}();$
 $\quad \text{gen}(E.addr \text{'=' } \mathbf{'minus'} E_1.addr); \}$

$\mid (E_1) \quad \{ E.addr = E_1.addr; \}$

$\mid \mathbf{id} \quad \{ E.addr = \text{top.get}(\mathbf{id.lexeme}); \}$

gen() does two things:

1. generate three address instruction
2. append it to the sequence of instructions generated so far

Three Address Code Generation

- Problems:

1. Change the semantic rules to generate three-address codes for arithmetic expressions (binary operators + and -) involving one-dimensional array variables on the right hand side.
 - Note that no array element will appear on the left hand side of an expression.
 - All variables used are integers of 4 byte length.

Write a program in any of your preferred language to generate the three-address code.
